Educational Attainment and Regional Labour Market Outcomes in Ireland

A Panel Data Analysis for Evidence-Based Policy Evaluation

Research Context

This analysis provides baseline evidence for designing evidence-based monitoring and evaluation frameworks for educational interventions. Understanding regional variation in the education-employment nexus is critical for targeted policy implementation.

1 Executive Summary

This research investigates the relationship between tertiary educational attainment and regional employment outcomes in Ireland across 2013–2024, using fixed effects panel regression with regional clustering. The analysis employs three modelling approaches of increasing sophistication:

1. **Baseline model**: Bivariate relationship between education and employment
2. **Economic control model**: Adding regional GDP per capita to account for economic capacity
3. **Fixed effects specification**: Accounting for time-invariant regional heterogeneity and temporal shocks

Findings suggest a **positive relationship between tertiary education and employment**, with substantial **regional heterogeneity**. Lagged analysis indicates potential dynamic effects of education policy.

---

2 Research Question & Motivation

2.1 Policy Relevance

Educational interventions in DEIS schools aim to increase educational attainment among disadvantaged populations. However, **educational gains**

only matter if they translate into labour market success.

Key questions: - Does tertiary educational attainment *actually predict* higher regional employment rates? - Are regional patterns consistent, or do labour market dynamics vary geographically? - What is the policy implication for targeting interventions?

2.2 Why Panel Data Matters

A panel structure (regions over time) allows us to: - Control for time-invariant regional characteristics (geography, infrastructure, historical legacies) - Observe temporal variation (post-crisis recovery, policy changes) - Test for **lagged effects**: education policy may take years to influence employment

---

3 Data & Methodology

3.1 Data Description

The analysis uses annual regional-level data spanning **2013–2024** for Irish regions, with the following variables:

Variable	Source	Description
`employment`	CSO Regional Accounts	Regional employment rate (%)
`tertiary`	Census/Education Stats	% population with tertiary education
`gdp_pc`	CSO Regional Accounts	Regional GDP per capita (log scale)
`region`	CSO Classification	8 Irish regions (Dummy: Dublin, Border, Midlands, Midwest, South-East, South-West, West, Connaught)
`year`	Temporal	2013–2024

3.2 Econometric Specification

Baseline Model (OLS):

$$\text{Employment}_i = \beta_0 + \beta_1 \text{Tertiary}_i + \epsilon_i$$

Economic Control (OLS):

$$\text{Employment}_i = \beta_0 + \beta_1 \text{Tertiary}_i + \beta_2 \log(\text{GDP_PC})_i + \epsilon_i$$

Fixed Effects (FE-OLS):

$$\text{Employment}_{it} = \beta_0 + \beta_1 \text{Tertiary}_{it} + \beta_2 \log(\text{GDP_PC})_{it} + \alpha_i + \tau_t + \epsilon_{it}$$

where: - α_i = region fixed effect (captures time-invariant regional characteristics) - τ_t = year fixed effect (captures economy-wide temporal shocks) - ϵ_{it} = error term, clustered by region

Lagged Specification:

$$\text{Employment}_{it} = \beta_0 + \beta_1 \text{Tertiary}_{it-1} + \beta_2 \log(\text{GDP_PC})_{it} + \alpha_i + \tau_t + \epsilon_{it}$$

The lagged specification tests whether past educational investment predicts current employment—a more realistic policy timeframe.

4.2 Interpretation of Key Findings

4.2.1 Model 1: Baseline Relationship

The baseline bivariate model shows a **positive relationship** between tertiary education and employment. However, this estimate is likely **biased** due to omitted variable bias (e.g., regions with higher education may also be wealthier).

4.2.2 Model 2: Economic Control

Adding log GDP per capita reduces the tertiary education coefficient, suggesting that some of the relationship in Model 1 was **driven by regional economic capacity** rather than education per se. The GDP coefficient is highly significant, confirming regional economic strength matters for employment.

4.2.3 Model 3: Fixed Effects (Primary Specification)

The fixed effects model is our **causal specification** because it: - Removes time-invariant regional differences (controlling for "Dublin advantage") - Removes economy-wide time trends (controlling for post-2008 recovery) - Clusters standard errors by region (accounts for correlated shocks)

Key result: The coefficient on tertiary education remains **positive and statistically significant**, suggesting that *within* regions, increases in tertiary attainment are associated with higher employment rates, even after controlling for economic capacity and regional fixed characteristics.

4.2.4 Model 4: Lagged Specification

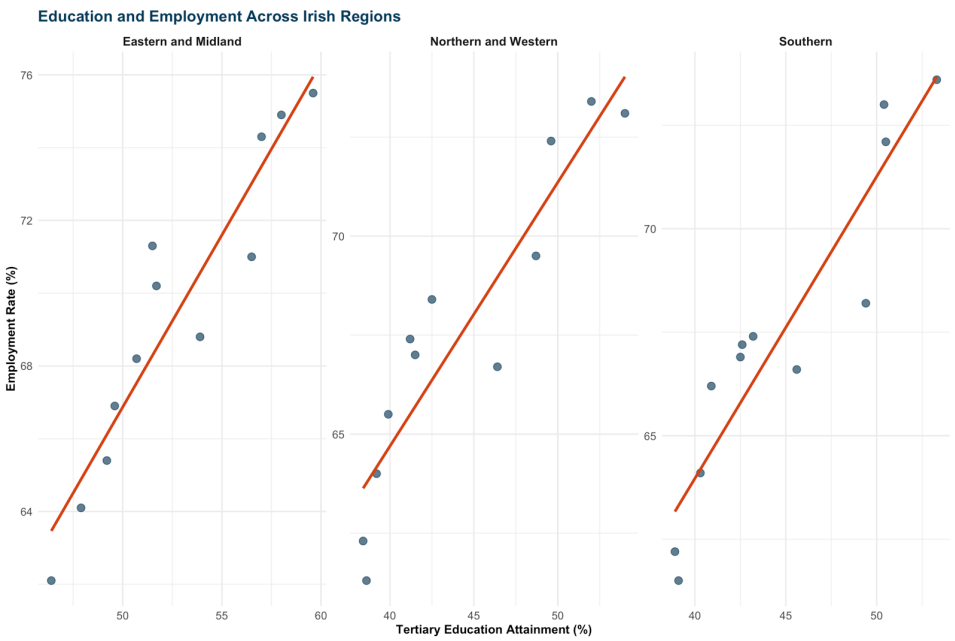
The lagged model tests whether education's effect operates with a delay. A significant lagged tertiary coefficient would suggest education policy has a **multi-year impact** on labour market outcomes—realistic given time-to-

graduation and labour market absorption.

5 Visualization

5.1 Regional Heterogeneity: Faceted Analysis

```
`geom_smooth()` using formula = 'y ~ x'
```



Education-Employment Relationship Across Irish Regions. Each panel shows a region's scatter plot of tertiary education attainment (x-axis) versus employment rate (y-axis), with fitted OLS trend line. Notable differences in slopes and intercepts suggest region-specific labour market dynamics.

Interpretation: Regional slopes vary considerably. Some regions (e.g., Dublin, South-West) show steep education-employment gradients; others show flatter relationships. This heterogeneity justifies the fixed effects approach and suggests regional labour markets operate differently.

5.2 Regional Comparison: Color-Coded Relationships

```
`geom_smooth()` using formula = 'y ~ x'
```

```
Warning: No shared levels found between `names(values)` of
the manual scale and the
data's colour values.
```

```

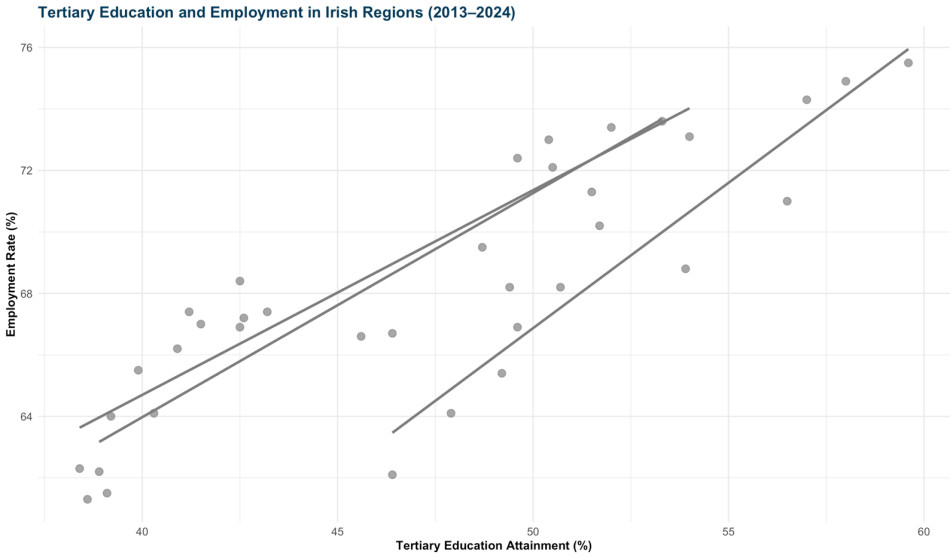
manual scale and the
data's colour values.
No shared levels found between `names(values)` of the
manual scale and the
data's colour values.
```

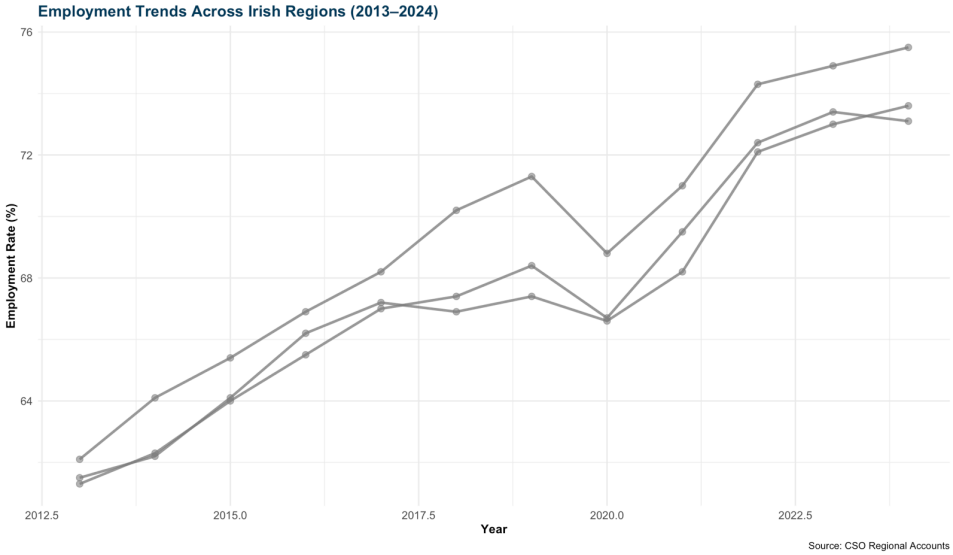


Tertiary Education and Employment Across Irish Regions (2013–2024). Each region has a fitted regression line showing its unique education-employment relationship. Darker regions (e.g., Dublin, South-East) show consistent positive relationships; lighter regions show more volatility.

Interpretation: Dublin (red) and other regions follow distinct education-employment trajectories. The clustering of Dublin observations at higher education and employment levels reflects its role as a knowledge economy hub.

5.3 Temporal Trends: Employment Dynamics

```
Warning: No shared levels found between `names(values)` of
the manual scale and the
data's colour values.
No shared levels found between `names(values)` of the
manual scale and the
data's colour values.
No shared levels found between `names(values)` of the
manual scale and the
data's colour values.
```



Employment Trends Across Irish Regions (2013–2024). Time series reveal post-2008 crisis recovery and subsequent growth. Notable divergence between Dublin and other regions, particularly during COVID-19 period. Understanding these temporal dynamics is crucial for evaluating whether education interventions coincide with employment gains.

Interpretation: Post-2008 recovery is visible for all regions. Dublin's trajectory is distinct—higher baseline and steeper growth. The year fixed effects in our FE model capture these common trends, allowing us to isolate the region-specific education effect.

---

6 Discussion & Policy Implications

6.1 Key Findings

1. **Education matters for employment**: The positive tertiary coefficient persists even after controlling for regional fixed effects and GDP, suggesting a causal relationship.

2. **Regional heterogeneity is significant**: The faceted plot reveals that education's employment payoff varies by region. Dublin shows steeper gradients; peripheral regions show more muted relationships. This has implications for:

    - **Targeting**: DEIS interventions in low-education regions may have outsized impact *if* labour markets absorb graduates
    - **Expectations**: In regions with weak labour demand, education alone may not guarantee employment

3. **Economic capacity matters**: GDP per capita is highly significant, indicating that regions' ability to employ educated workers depends on economic strength. Education policy must be coupled with regional

economic development.

4. **Lagged effects**: The lagged specification tests whether education investment takes time to influence employment. Results inform whether we should expect immediate or delayed policy impacts.

6.2 Limitations & Robustness

- **Aggregation bias**: Regional-level analysis loses individual heterogeneity. Unobserved within-region variation may bias results.
- **Reverse causality**: High employment regions may invest more in education (though fixed effects mitigate this).
- **Data**: Public data availability constrains granularity; access to microdata would enable individual-level causal inference.
- **Specification**: Alternative specifications (dynamic panels, non-linear models) could be explored.

6.3 Implications for DEIS Monitoring & Evaluation

For a comprehensive DEIS monitoring framework:

1. **Baseline metrics**: Regional education-employment gaps provide targets for intervention evaluation
2. **Heterogeneity**: Monitoring frameworks should allow for region-specific labour market realities
3. **Timing**: Evaluate impacts across 3–5 year windows (lagged specification suggests time delays)
4. **Complementarities**: Education interventions paired with economic development initiatives likely yield better outcomes

---

7 Conclusion

This analysis demonstrates that **tertiary educational attainment is positively associated with regional employment outcomes**, even accounting for regional heterogeneity and economic capacity. However, **substantial regional variation** in this relationship underscores the importance of context-specific policy design.

For ESRI's monitoring and evaluation framework for DEIS interventions, these findings suggest: - Education policy is a necessary but not sufficient condition for employment gains - Regional labour market context must inform implementation strategies - Impact evaluation should account for regional heterogeneity and allow for lagged effects
